

**EN530.603 Applied Optimal Control**  
**Homework #4**  
October 22, 2014

Due: November 5, 2014 (before class)

Professor: Marin Kobilarov

1. Consider the minimization of

$$J = \frac{1}{2}x(1)^2 + \int_0^1 \frac{1}{2}[x(t)u(t)]^2 dt,$$

subject to the nonlinear dynamics

$$\dot{x} = xu, \quad x(0) = 1.$$

Derive an optimal feedback control using the HJB equation. In the process, show that the HJB partial differential equation has a solution that is a quadratic function in  $x$ .

2. Consider the LQR problem with known disturbance  $w(t)$  which requires the minimization of

$$J = \frac{1}{2}x(t_f)^T P_f x(t_f) + \frac{1}{2} \int_{t_0}^{t_f} [x(t)^T Q(t)x(t) + u(t)^T R(t)u(t)] dt,$$

subject to

$$\dot{x}(t) = A(t)x(t) + B(t)u(t) + w(t).$$

- a) Using the HJB equation, show that a possible value function has the form

$$V(x(t), t) = \frac{1}{2}x(t)^T P(t)x(t) + b(t)^T x(t) + c(t)$$

and show that the associate optimal control is

$$u(t) = K(t)x(t) + k(t),$$

where  $K(t)$  and  $k(t)$  are the feedback gain matrix and feedforward term, respectively. Derive the differential equations for  $\dot{P}$ ,  $\dot{b}$ ,  $\dot{c}$  and their boundary conditions which satisfy the HJB equation.

- b) Do the discrete-time equivalent of a)
3. Read the paper: J. Betts “Survey of Numerical Methods for Trajectory Optimization”, Journal of Guidance, Control, and Dynamics, Vol. 21, No. 2, 1998
4. Nonlinear numerical optimal control implementation:

- a) An example of a direct shooting method is provided with an example application to a simple car model (`car_shooting.m`) that exploits the least-squares structure of the cost function. You are required to apply the same method to a new system of your choice, or to the two-link arm example with discrete dynamic function  $f_k$  given in file `arm_sim.m`. *Details:* this problem is implemented using the Gauss-Newton (GN) least-squared method for optimizing over the controls  $\xi \triangleq u_{0:N-1}$ . Using the dynamics each state can be expressed as a function of  $\xi$  which is encoded through the functions  $x_k = \psi_k(\xi)$  for  $k = 0, \dots, N$ . The cost is then expressed as  $J(\xi) = \frac{1}{2}g(\xi)^T g(\xi)$ , where  $g(\xi)$  is given by

$$g(\xi) = \begin{bmatrix} \sqrt{R_0}(u_0 - u_d) \\ \sqrt{Q_1}(\psi_1(\xi) - x_d) \\ \sqrt{R_1}(u_1 - u_d) \\ \vdots \\ \sqrt{Q_{N-1}}(\psi_{N-1}(\xi) - x_d) \\ \sqrt{R_{N-1}}(u_{N-1} - u_d) \\ \sqrt{Q_f}(\psi_N(\xi) - x_f) \end{bmatrix},$$

for some desired control  $u_d$ , desired state  $x_d$ , and desired final state  $x_f$ . Since  $R_k > 0$  the Jacobian  $\partial g(\xi)$  is guaranteed to be full rank and one can apply a GN iterative method directly to update  $\xi \rightarrow \xi + \delta\xi$  where  $\delta\xi = -(\partial g^T \partial g)^{-1} \partial g^T g$ . In addition, the Jacobian has a lower-triangular structure that can be exploited in the Cholesky GN solution.

- b) A general discrete optimal control code (`ddp.zip`) is provided along with two examples (2-dof robotic arm and a second-order wheeled vehicle model). You have two options: 1) *extend* one of the two provided models; or 2) implement a new model of your own choice in a similar manner as the two examples. In both cases you must include meaningful control bounds (by modifying `ddp.m`) and add environmental obstacles (recall HW3#3). Obstacles should be added as a penalty/repulsive potential term to the cost function. In your plots clearly show that the computed controls do not exceed the specified bounds. *Details:* Assume that we need to enforce a constraints of the form

$$c_k(x_k, u_k) \leq 0, \text{ for all } k = 0, \dots, N-1,$$

where  $c_k = (c_k^1, \dots, c_k^m)$  are  $m$  constraint functions. This can be accomplished by adding penatly terms to the trajectory costs  $L_k$ , i.e. by using

$$\bar{L}_k(x, u) = L_k(x, u) + \frac{\beta_k}{2} \|g_k(x, u)\|^2,$$

in place of  $L_k(x, u)$ , where  $g_k(x, u) = \max(c_k(x, u), 0)$  for some chosen coefficient  $\beta_k > 0$  that controls the “softness” of the constraint (here max is applied independently to each component of the vector  $c_k$ ). Then the Jacobian with respect to  $x$  is

$$\nabla_x \bar{L}_k(x, u) = \nabla_x L_k(x, u) + \beta_k \partial_x g_k(x, u)^T g_k(x, u),$$

and is similarly defined with respect to  $u$ . The Hessian is

$$\nabla_x^2 \bar{L}_k(x, u) = \nabla_x^2 L_k(x, u) + \beta_k \partial_x g_k(x, u)^T \partial_x g_k(x, u) + \beta_k \sum_{i=1}^m g_k^i(x, u) \nabla_x^2 g_k^i(x, u)$$

and is similarly defined with respect to  $u$ . In some cases (when either  $g_k$  is small or  $\nabla_x^2 g_k^i(x, u)$  has small eigenvalues) the last term above can be ignored.

See example `ddp_pnt_obst.m`

- c) Implement a nonlinear programming strategy using direct transcription/collocation (as explained in the notes and also in Betts, 1998) to one of the two provided models (car or arm), or to a model of your choice. This can be accomplished by defining the cost and constraints and finding a solution using Matlab `fmincon`. See example `trajopt_sqp_car.m`. Obstacles should be added as inequality constraints.

Note: email your code to `marin@jhu.edu` with a subject line starting with: **EN530.603.F2014.HW4**; in addition attach a printout of your code and *plots* (annotated if necessary) to your homework solutions.
